

A particle is projected vertically upwards with a speed of  $30 \text{ ms}^{-1}$  from a point A. The point B is  $h$  metres above A. The particle moves freely under gravity and is above B for 2.4 seconds. Calculate the value of  $h$ .

The particle reaches a highest point. Let's call it C. At this point  $v = 0$ . The journey from B to D takes 2.4 seconds so the journey from B to C takes 1.2 seconds

There are two ways of doing this

### Method 1

Consider the journey from A to C

$$s = \quad u = 30 \quad v = 0 \quad a = -9.8 \quad t = ?$$

Let's find  $t$

$$v = u + at \text{ leads to } t = \frac{150}{49}$$

The journey from B to C takes 1.2 seconds (ask me if you don't understand)

$$\text{So the journey from A to C takes } \frac{150}{49} - 1.2 = \frac{456}{245}$$

Now consider the journey from A to C

$$s = h \quad u = 30 \quad v = \quad a = -9.8 \quad t = \frac{456}{245}$$

$$s = ut + \frac{1}{2}at^2 \text{ leads to } h = 38.86 = 39 \text{ m (2 s.f.)}$$

### Method 2

Consider the journey from B to C

$$s = \quad u = ? \quad v = 0 \quad a = -9.8 \quad t = 1.2 \text{ (ask me if you don't understand)}$$

$$v = u + at \text{ leads to } u = \frac{294}{25}$$

Consider the journey from A to B

$$s = h \quad u = 30 \quad v = \frac{294}{25} \quad a = -9.8 \quad t =$$

$$v^2 = u^2 + 2as \text{ leads to } h = 38.86 = 39 \text{ m (2 s.f.)}$$
